

The 'concept' or strategy for each zone describes future management aspirations. It takes into account local qualities, resources and sensitivities.

Riparian zones of main water bodies & their immediate setting
Tailor restock design to reflect the ecological sensitivity & amenity value of these zones with a focus on UKFS & 'drinking water supply' best practice;
Maintain &, where budgets allow, enhance visitor services infrastructure;
At Burncrooks reservoir we will plant low density native woodland along the John Muir Way to diversify & enhance this promoted trail & riparian zone (total planting 6.35ha).

Whole plan area - Windblow & Larch
The 10 year plan of operations will aim to:
Restructure remaining mature conifer plantations with spreading windblow.
Manage the threat of Phytophthora ramorum by removing mature larch & securing access to pre-commercial larch stands.
(A proportion of mature conifer areas, without Larch, will be retained as long-term retentions to improve age class diversity & for conservation)

Core sustainable timber production zones.
We will continue to restructure forest stands to....
Maintain a core supply of marketable timber products;
Improve operational & visual design;
Protect water supply infrastructure & enhance catchment zones;
Extend ride networks & windfirm coupe boundaries - to improve forest resilience & age restructuring potential;
Expand the network of mixed woodlands managed at lower intensity for conservation, water quality & amenity;
Protect &, where practical, enhance the setting of heritage features & important path networks (e.g. core paths, John Muir Way).
To deliver these outcomes we will maintain a number of forest quarries supplying stone for management access.

*Ancillary objectives will be delivered based on site specific factors:
Diversify timber producing tree species;
Expand & maintain native woodlands;
Thin forest stands & use alternatives to clearfell;
Restore priority open habitats.*

Expand native woodland restocking to link with existing ancient woodland.

Continue to enhance forest design along John Muir Way.

Whole plan area - Deer Management
The deer management plan's objective is to regulate browsing levels to ensure regeneration of forest stands.
Current control levels will be reviewed & adjusted annually based on deer population and tree condition surveys.
Deer fencing will be removed to allow more active deer control operations to progress.

Dumbarton Muir & Saughen Braes
Continue to manage as a remote upland landscape of open habitats & occasional peat fringe woodland.
Continue peat restoration to connect & enhance existing priority habitats. Control deer populations & gradually remove deer fencing. Protect & maintain the John Muir Way. Protect heritage features & carry out agreed management to protect nationally important conservation sites, namely Dumbarton Muir & Lily Loch SSSIs.

Duncolm Hills
Continue to manage as a remote upland landscape of low density native woodland & successional open space. Gradually remove deer fencing & control deer populations to allow establishment of young native woodland.
Protect heritage features & public access routes, enhancing immediate setting through forest design where practical.
Investigate access improvements to facilitate management across the plan area with possible forest road linkage between Auchineden & Auchentorlie sub-blocks.

Plant low density native woodland to enhance John Muir Way & Burncrooks reservoir riparian zones. 50% woodland to 50% open space. Total planting 6.35 hectares.

Protect dry heath habitat on Lang Craigs plateau. Sensitive forest design considering visible forest edges, open habitats & geological formations.

Diversify productive species in more sheltered zones with brown earth soils.

Sensitive forest design to soften visible forest edges & accentuate volcanic landforms.

Kilpatrick Braes & Cochno Hills - upper slopes & summits
Recognising the value of this zone for landscape & recreation we will use minimum intervention management:
1. Summits & higher slopes will be left as successional open & scrub habitats;
2. Lower slopes left as low density native woodland habitat.

Kilpatrick Braes, Cochno Hills & Old Kilpatrick - lower slopes.
Recognising the value of this zone for landscape, recreation, heritage & conservation we will retain existing woodlands under lower intensity management systems. Tree species composition will be primarily native with some mixed LEPO stands, & alternative conifers. Except for the removal of Larch, LEPO stands will be managed through minimum intervention. Minor access facilities will be installed to allow thinning of alternative conifers for their long term stability. The 'Antonine Wall' & its immediate setting will continue to be managed in compliance with the WHS management plan. Visitor services infrastructure will be maintained &, where budgets allow, enhanced.

Young broadleaved woodlands to be managed at lower intensity as a more permanent link between LEPO & ancient woodland habitats.
